NP10 8QQ

I, the undersigned, being an officer duly authorised in accordance with Section 74(1) and (4) of the Deregulation & Contracting Out Act 1994, to sign and issue certificates on behalf of the Comptroller-General, hereby certify that annexed hereto is a true copy of the documents as originally filed in connection with the patent application identified therein.

In accordance with the Patents (Companies Re-registration) Rules 1982, if a company named in this certificate and any accompanying documents has re-registered under the Companies Act 1980 with the same name as that with which it was registered immediately before re-registration save for the substitution as, or inclusion as, the last part of the name of the words "public limited company" or their equivalents in Welsh, references to the name of the company in this certificate and any accompanying documents shall be treated as references to the name with which it is so re-registered.

In accordance with the rules, the words "public limited company" may be replaced by p.l.c., plc, P.L.C. or PLC.

Re-registration under the Companies Act does not constitute a new legal entity but merely subjects the company to certain additional company law rules.

Warning

After an application for a patent has been filed, the Comptroller of the Patent Office will consider whether publication or communication of the invention should be prohibited or restricted under Section 22 of the Patents Act 1977. You will be informed if it is necessary to prohibit or restrict your invention in this way. Furthermore, if you live in the United Kingdom, Section 23 of the Patents Act 1977 stops you from applying for a patent abroad without first getting written permission from the Patent Office unless an application has been filed at least 6 weeks beforehand in the United Kingdom for a patent for the same invention and either no direction prohibiting publication or communication has been given, or any such direction has been revoked.

Notes

- If you need help to fill in this form or you have any questions, please contact the Patent Office on 08459 500505.
- Write your answers in capital letters using black ink or you may type them.
- If there is not enough space for all the relevant details on any part of this form, please continue on a separate sheet of paper and write "see continuation sheet" in the relevant part(s). Any continuation sheet should be attached to this form.
- If you have answered 'Yes' Patents Form 7/77 will need to be filed.
- Once you have filled in the form you must remember to sign and date it.
- For details of the fee and ways to pay please contact the Patent Office.

Patents Form 1/77

Smoking article and apparatus and process for manufacturing a smoking article

This invention relates to smoking articles, and in particular to smoking articles having flavourant material therein.

Flavourant materials such as menthol have been applied to smoking articles to modify the smoke and taste characteristics thereof. Flavourant materials have been added to smoking articles by various methods, for example by spraying a flavourant-containing solution onto tobacco or by applying flavourant material to the cigarette wrapper. However, due to the volatile or semi-volatile nature of many flavourant materials a significant amount of the flavourant material is lost via evaporation during the manufacture and storage of the smoking articles. Further, during smoking, more flavourant material is volatilised by the smoke in the initial puffs, resulting in uneven provision of the flavourant material to the consumer.

In order to prevent loss or premature volatilisation of the flavourant material various substances have been utilised to encapsulate the flavourant material. A number of flavourant encapsulation techniques involve encapsulation of a flavourant material within a polysaccharide coating. For example, EP 0 490 559 discloses a filament comprising a core of flavourant material and polysaccharide binder with a coextensive alginate sheath coating. It is however difficult to insert such a filament into a cigarette using conventional high speed machinery. The control of flavour delivery to the consumer at specific stages during smoking is also not easily achieved using such filaments due to a necessity for precise positioning of the flavourant material in a cigarette.

A further encapsulation technique for smoking articles involves microencapsulation of a flavourant material, and incorporation of the microcapsules into a tobacco blend. Disadvantages of such a technique include the difficulty in attaining an even distribution of microcapsules in the smoking article if desired, or alternatively the difficulty in precisely positioning the microcapsules in a specific location in a smoking article.

Adsorbent material having a microporous structure also possesses stabilising qualities and is able to retain flavourant material and allow the flavourant material to be released upon heating to a given temperature, such as for example during smoking.

US 3,150,668 describes a cigarette having flavourant therein to convey to the consumer the point at which smoking should be ceased. A retarding agent is employed with the flavourant to prevent flavourant reaching the consumer during the initial puffs of the cigarette. The retarding agent is in liquid or solid form and may be activated carbon. The flavourant and retarding agent are mixed together before being constructed into a cigarette. However, the mixture is not easily positioned at a location within a cigarette, particularly at the high speeds used in cigarette manufacture.

It is considered to be advantageous to be able to simply and effectively position a stabilised flavourant material in a smoking article and particularly towards one end of a smoking article only so that upon smoking the consumer will encounter a flavour sensation during the final puff or final few puffs. Ideally the flavourant material will provide a refreshing taste and will provide a "fresh finish" to the consumer.

It is an object of the present invention to provide a smoking article having stabilised flavourant for delivery to the consumer during smoking.

It is a further object of the present invention to provide a smoking article having a precisely positioned stabilised flavourant therein.

It is a further object of the present invention to provide a process and apparatus for producing a smoking article having a stabilised flavourant located therein.

It is an even further object of the present invention to provide a flavour sensation in the final puff(s) of the smoking article.

The present invention provides a smoking article comprising a rod of smokable material and a web material, the web material containing an adsorbent material and a flavourant material.

Preferably the smoking article comprises a wrapper. It is by preference that the rod of smokable material is wrapped in a wrapper. The wrapper is suitably a conventional cigarette paper, for example.

The smoking article may be wrapped in more than one wrapper, and may be, for example, double wrapped. It is preferred however that the smoking article is wrapped in a single wrapper.

It is by preference that the smoking article comprises a filter element. The filter element may be a multiple filter comprising multiple sections such as, for example, a dual or triple filter. Suitable filters are well known to those skilled in the art.

Preferably the web material is a fibrous sheet material. More preferably the fibrous sheet material is a cellulosic sheet material or a tobacco-containing sheet material. The fibrous sheet material is advantageously a cellulosic web material. More advantageously the cellulosic web material is a paper web material. Advantageously the adsorbent material is incorporated within the web material, the adsorbent being an integral component of the web material.

It is by preference that the adsorbent material comprises the flavourant material. Suitably the adsorbent material is one or more of the following: zeolite, sepiolite, clay, activated alumina, mineral, resin, carbon. Preferably the adsorbent material is carbon. More preferably the adsorbent material is activated carbon.

Advantageously the adsorbent material is in granular, powder or particulate form. Where the adsorbent material is in granular, powder or particulate form, the adsorbent material preferably has a particle size of less than 500 μ m and is preferably less than 100 μ m. More preferably the adsorbent material has a particle size of less than 20 μ m and most preferably has a particle size of about 15 μ m. The particle size is considered to be the diameter of the particle.

Suitably the level of loading of the adsorbent material in the web material is less than 70% by weight of the web material. Preferably the level of loading of the adsorbent material in the web material is less than 50% by weight of the web material. Advantageously the adsorbent material loading in the web material is 20-45% by weight of the web material.

When the adsorbent material is activated carbon it is preferred that the carbon has a level of activity of 0-160% CTC. More preferably the carbon has an activity of 40-130% CTC. Activity of carbon is measured in per cent carbon tetrachloride (CTC), a measurement well known in the art. Carbon is weighed, exposed to CTC and the weight of the carbon subsequently remeasured. The increase in weight of the carbon is calculated as a percentage.

Suitably the flavourant material is a volatile or semi-volatile flavourant. Flavourant materials suitable for use in the smoking article of the present invention include: menthol,

alcohols, esters, ketones, lactones, essential oils, and aldehydes. A commonly used flavourant material is menthol.

Preferably the smokable material is a tobacco material. Suitably the tobacco material comprises one or more of stem, lamina, tobacco dust. It is preferred that the tobacco material comprises one or more of the following types: Virginia or flue-cured tobacco, Burley tobacco, Oriental tobacco, reconstituted tobacco. It is much by preference that the smokable material comprises a blend of tobacco material. Advantageously the smokable material comprises 10-80% Virginia tobacco, 10-60% Burley tobacco, 0-20% Oriental tobacco, 0-20% reconstituted tobacco and 0-30% expanded tobacco.

Preferably the web material is positioned adjacent to the rod of smokable material. Advantageously the web material is located between the rod of smokable material and the wrapper surrounding the rod of smokable material. Even more advantageously the web material is adhered to a surface of the wrapper, which surface is a surface facing the rod of smokable material. The web material is suitably adhered to the wrapper by an adhesive. Preferably the adhesive is one of the following: a heat-activatable adhesive, PVA, starch, starch solution. Advantageously the adhesive is starch solution.

Alternatively, the web material can be contained within the smokable material, such that the rod of smokable material comprises the web material therein. Preferably the web material forms part of the blend of smokable material. In such a case the web material is of a size that allows the web material to be blended with the smokable material. Suitably the web material is cut to 20-50 cuts per inch (cpi). Preferably the web material is cut to 30-35 cpi. Suitably the shredded web material is incorporated in the smokable material in an amount of 10-30% by weight of the smokable material. More preferably the shredded web material is incorporated in the smokable material in an amount of approximately 20% by weight of the smokable material.

In both of the above alternatives it is preferred that the web material extends over only a portion of the length of the smoking article. It is much by preference that the web material extends over only a portion of the smoking article at the mouth end of the smoking article.

The web material extends wholly or partly along the length of the rod of smokable material. If it is desired to deliver flavourant at a specific point during the smoking of the smoking article the web material preferably extends only partly the length of the rod of smokable material. Preferably the web material extends 10-60% of the length of the rod of suitable material. In a first aspect the web material extends from a point at the mouth end of the smoking article to a point towards the end away from the mouth end. Advantageously the point towards the end away from the mouth end is a point 10-60% of the distance along the rod of smokable material from the mouth end of the smoking article. In a second aspect the web material extends from a first point towards the mouth end of the smoking article to a second point towards the end of the smoking article away from the mouth end thereof. Preferably the first point towards the mouth end of the smoking article is a point at least 10% of the distance along the rod of smokable material from the mouth end of the smoking article. Further it is preferred that the second point towards the end of the smoking article away from the mouth end thereof is a point 11-60% of the distance along the rod of smokable material from the mouth end of the smoking article. Two or more regions of web material may extend along the length of the rod of smokable material.

The present invention further provides a method of applying flavourant to a web material, the web material comprising an adsorbent material, wherein the web material is fed along a transport path and a flavourant is applied to a surface of the web material as it travels along the transport path.

Preferably the flavourant is applied to the web material by a flavourant applicator means. Preferably flavourant is applied to the surface of the web material as a stream of flavourant. More preferably flavourant is applied to the web material as a plurality of streams of flavourant. Suitably the plurality of streams of flavourant is applied to the web material in a line or in an array. When applied in an array the array comprises two lines of streams of flavourant, one of the lines being offset from the streams of flavourant in an adjacent line. Suitably flavourant is applied to a surface of the web material as 1-30 streams of flavourant. Advantageously flavourant is applied to a surface of the web material as 8-14 streams of flavourant. Suitably each stream of flavourant has a cross-section substantially corresponding to

the shape of an orifice in the applicator means through which the flavourant is passed. Preferably each stream of flavourant is in the form of a filament and has a substantially circular cross-section.

If the flavourant is solid at room temperature the flavourant is preferably heated to maintain the flavourant in a molten liquid state. Advantageously the flavourant is heated to a temperature of 40-55°C. It is preferable that the flavourant is heated by the applicator means, in particular by a supply means of the applicator means, the supply means being operable to supply flavourant from a flavourant source to an applicator head operable to apply flavourant to the web material.

Suitably the web material is fed from a first web material holding means to a second web material holding means. Preferably the first and/or second web material holding means comprises a mandrel. Preferably the web material is fed from an unwind mandrel and is fed to a rewind mandrel.

Preferably the web material is fed to a guide roller along the transport path, the web material being guided by the guide roller along the transport path. More preferably the web material is fed to a plurality of guide rollers along the transport path.

Preferably the adsorbent material is carbon, and is even more preferably activated carbon. Advantageously the adsorbent is in granular, powder or particulate form.

Preferably the flavourant is a volatile or semi-volatile flavourant. Suitably the flavourant is in liquid or molten state. Preferably the flavourant is one or more of the following: alcohol, ester, ketone, lactone, essential oil, aldehyde, or menthol. Advantageously the flavourant is menthol.

Preferably the web material is a fibrous sheet material. More preferably the web material is a cellulosic or tobacco-containing sheet material. Advantageously the web material is paper.

Preferably the web material undergoes an equilibration stage after application of flavourant thereto, which stage involves allowing the flavourant applied to the web material to equilibrate in the web material. This stage is known as the "bulking" stage. Suitably the web material is stored for a period of time to allow equilibration of the flavourant in the web

material at a temperature operable to promote equilibration of the flavourant in the web material.

The present invention also provides an apparatus for applying flavourant to a web material, the web material comprising an adsorbent material, the apparatus comprising first web material holding means, applicator means capable of applying flavourant to the web material and second web material holding means.

Preferably the applicator means comprises an applicator head for application of the flavourant to the web material and a supply means for supplying flavourant to the applicator head.

Preferably the applicator head has an opening in a surface thereof through which flavourant may be passed. More preferably the applicator head has a plurality of openings in a surface thereof. Advantageously the applicator head has 1-30 openings in a surface thereof. More advantageously the applicator head has 8-14 openings in a surface thereof. Suitably an opening in a surface of the applicator head is circular or elongated. Preferably the openings are located in a removable plate. Suitably the openings are arranged in a line or in an array, the array comprising two lines of openings in which the openings in one of the two lines are offset from the openings in an adjacent line.

Suitably the applicator means comprises heating means to heat the flavourant and maintain the flavourant in a molten liquid state. It is by preference that the heating means heats the supply means. Most preferably the supply means is heated to a temperature of 40-55°C.

Preferably the first and/or second holding means comprises a mandrel. More preferably the first holding means is an unwind mandrel and the second holding means is a rewind mandrel. The unwind mandrel serves to feed the web material thereon therefrom and the rewind mandrel receives the web material that is fed thereto. It is preferred that the rewind mandrel is driven.

Suitably the web material comprising an adsorbent material is in the form of a bobbin. Preferably the bobbin is held by the first holding means.

Preferably the apparatus comprises a guide roller, which guide roller controls the path of the web material. More preferably the apparatus comprises a plurality of guide rollers. Advantageously the or each guide roller is in contact with the web material.

Suitably a first guide roller is positioned such that web material fed from the first holding means is fed around the first guide roller. A second guide roller is positioned such that web material is fed around the second guide roller after being fed around the first guide roller and before the web material reaches the applicator means. Preferably a third guide roller is positioned such that the web material is fed around the third guide roller after having flavourant applied thereto and before being received by the second holding means.

It is preferred that the apparatus comprises a brake arm assembly. The brake arm assembly is in contact with a guide roller. Preferably the brake arm assembly is in contact with a plurality of guide rollers. The brake arm assembly is movable and ensures that the web material is maintained at a given tension. The brake arm assembly is contactable with the first holding means. Preferably the brake arm assembly contacts a drum of the first holding means. The degree of pressure exerted by the brake arm assembly on the drum controls the tension of the web material being fed from the first holding means. When the web material is under tension an end of the brake arm assembly away from the first holding means is raised, pivoting the end of the brake arm assembly contactable with the drum of the first holding means away therefrom. In contrast, when the web material leaving the first holding means is under insufficient tension the end of the brake arm assembly away from the first holding means and contactable with a guide roller is in a lowered position and accordingly the end of the brake arm assembly contactable with the first holding means is pressed against the drum of the first holding means, the pressure on the drum slowing the feed of the web material from the first holding means.

Suitably the apparatus comprises an encoder. The encoder is preferably positioned along the web feed path before the location of the applicator means. Preferably the encoder is in contact with the web material along the web feed path and is able to measure the speed of feed of the web material. Advantageously the encoder is in communication with the second holding means and/or a motor means that drives the second holding means. As the speed of feed of the

web material is communicated to the second holding means and/or motor means that drives the second holding means the speed at which the second holding means is driven and receives web material is varied such that a constant web material speed is maintained.

The present invention also provides a method of making a smoking article according to the present invention.

Preferably web material, the web material comprising an adsorbent material and a flavourant, is fed from a web material holding means along a feed path to a cutting means, the web material being cut by the cutting means into sections, the sections being transferred by an assembly to a wrapper.

Preferably the web material is cut into sections of a specified length, for example by a rotary knife assembly. It is preferred that the web material is cut to a length corresponding to twice the length of web material in the smoking article product. The section of web material after being applied to a wrapper will then be constructed into a double length smoking article, which article is subsequently cut to form two smoking articles of the desired length and having a section of web material in each of the smoking articles of the desired length. Preferably the length of the web material section in the finished smoking article corresponds to 40-60% of the length of the rod of smokable material of the smoking article. Accordingly it is preferred that the web material is cut to a length corresponding to 80-120% of the length of the rod of smokable material of the finished smoking article.

Alternatively the web material is cut into sections having a length less than the length of the smoking article. Even more advantageously the web material is cut to a length corresponding to half the length of the smoking article or less. In this alternative embodiment the section of web material is not subsequently cut in a further step during the making of a smoking article on a smoking article making machine. This alternative embodiment is preferred for smoking articles in which the web material is positioned at a distance from the mouth end of the rod of smokable material, a double-length web material section not being suitable for such a position of the web material in the smoking article.

Suitably adhesive is applied to a surface of the web material. Preferably adhesive is applied to a surface of the web material by an adhesive applicator. It is by preference that the

adhesive applicator is located along the feed path before the cutting means. The surface having adhesive applied thereto is applied to a surface of a wrapper, the wrapper being, for example, a cigarette paper or a plugwrap. Advantageously the web material is applied to a surface of the wrapper at a location corresponding to the mouth end of the smoking article.

Alternatively adhesive is applied to a surface of a wrapper by an adhesive applicator. Preferably the surface of the wrapper having adhesive applied thereto is a surface to which a section of web material is applied. Advantageously the adhesive is applied to a surface of the wrapper at a location corresponding to the mouth end of the smoking article in the finished product.

The method further comprises supplying a wrapper to a wrapper feed path such that the wrapper may have sections of web material transferred thereto. Suitably the wrapper feed path is adjacent an assembly capable of transferring sections of web material to the wrapper. Preferably the wrapper feed path is in contact with the assembly capable of transferring sections of web material to the wrapper.

Suitably the assembly that transfers sections of the web material to the wrapper is a vacuum assembly. Preferably the vacuum assembly comprises a suction drum. The sections of web material are held on a surface of the suction drum by a suction force. Preferably the vacuum assembly accelerates the sections of web material during transfer of the sections of web material to the wrapper. More preferably the vacuum assembly accelerates the sections of web material to a speed equal to that of the wrapper.

Preferably the wrapper is fed to a smoking article making machine such as a cigarette making machine.

Preferably the wrapper feed path comprises guide means to allow the wrapper to be precisely aligned with the sections of web material being transferred thereto. More preferably the guide means is a paper tracking guide.

Suitably adhesive is applied over the entire surface of the web material or over only a part thereof. When applied over only a part of a surface of the web material it is preferred that the adhesive is applied in a strip towards an edge of the web material. Preferably adhesive is applied in a strip along an edge of the web material. Alternatively adhesive is applied in a strip

positioned at a distance from the edge of the web material, the strip being parallel to the edge of the web material. Advantageously adhesive is applied in a strip at each longitudinal edge of the web material. Preferably the or each strip of adhesive is about 2mm wide. When the adhesive is applied in a strip positioned at a distance from the edge of the web material it is preferred that the adhesive is positioned at a distance of about 2mm from an edge of the web material.

Alternatively, the web material is cut to a specified length and is applied to a wrapper, the web material and wrapper having pressure applied thereto to adhere the web material to the wrapper. In this aspect no adhesive is used to adhere the web material to the wrapper. Suitably a pinch belt is used to apply pressure to the web material and wrapper. Preferably pressure is applied to the web material and wrapper from each side thereof. Preferably two pinch belts are used, a pinch belt being positioned on each side of the wrapper.

When adhesive is used to adhere the web material to the wrapper it is preferable that the wrapper feed path comprises a heater means. Preferably the heater means permanently bonds the section of web material to the wrapper. If heat activatable adhesive is used to adhere the section of web material to the wrapper the heater means activates the heat-activatable adhesive. The heater means may be used to remove unbound flavourant from the web material.

The present invention provides an apparatus for producing a smoking article according to the present invention comprising means for supplying a web material containing an adsorbent and a flavourant, cutting means for cutting the web material into lengths, an assembly for transferring lengths of web material onto a wrapper, adhering means to bond the web material onto the wrapper, and cigarette forming means.

The present invention further provides an apparatus for applying web material onto a wrapper, the web material containing an adsorbent material and a flavourant, the apparatus comprising means for supplying a web material containing an adsorbent and a flavourant, cutting means for cutting the web material into lengths, an assembly for transferring the lengths of web material to the wrapper, and adhering means for bonding the web material to the wrapper.

Preferably the means for supplying the web material is a mandrel. Suitably the mandrel is capable of holding a bobbin of web material.

Preferably the cutting means comprises a housing and a knife. Suitably the knife is mounted on the housing. Preferably the housing is rotatable. Advantageously the cutting means comprises a plurality of knives. More advantageously each of the plurality of knives is spaced equidistantly on the housing.

Suitably the assembly for transferring lengths of web material onto a wrapper is positioned adjacent to the cutting means. Preferably the cutting means is in contact with the assembly for transferring lengths of web material onto a wrapper such that the web material is cut into lengths against the assembly for transferring lengths of web material onto a wrapper. Preferably the assembly for transferring lengths of web material onto a wrapper is a vacuum assembly. More preferably the assembly for transferring lengths of web material onto a wrapper comprises a suction drum. Advantageously the assembly for transferring lengths of web material onto a wrapper is operable to accelerate lengths of web material to a greater speed. Preferably the greater speed is approximately equal to a speed at which the wrapper is moving.

In a first aspect of the invention the adhering means comprises an adhesive applicator. Preferably the adhesive applicator comprises a roller and an adhesive source. The roller is in contact with the adhesive source and is operable to transfer the adhesive from the adhesive source to the web material. More preferably the adhesive applicator comprises first and second rollers. Suitably the first roller is in contact with the adhesive source and the second roller and is operable to transfer adhesive from the adhesive source to the second roller, which second roller is operable to transfer adhesive from the first roller to the second roller. Advantageously the adhesive applicator is able to apply adhesive in various patterns to the web material. Suitably the first roller has a channel therein capable of containing adhesive. Adhesive is transferred from the channel of the first roller to the second roller. Preferably the first roller has a plurality of channels therein, and advantageously has only two channels therein. It is preferred that the first roller has two channels therein, which channels correspond to positions on the second roller that will apply adhesive to the edges of the web material, or to regions towards the edges of the web material.

Preferably the apparatus comprises a means to feed the web material along a web material feed path. More preferably the means to feed the web material is a metering roller. The

metering roller advantageously controls the speed at which web material is fed along the web material feed path. Suitably the metering roller is adjacent a rubber roller and positioned such that the metering roller and rubber roller are capable of feeding web material therebetween.

It is preferred that the apparatus comprises a tracking means. It is more preferred that the tracking means is a paper tracking means to align the web material with the cutting means. Advantageously the tracking means is positioned on the feed path of the web material before the cutting means. Preferably the apparatus comprises a further tracking means to align a wrapper with the assembly for transferring lengths of web material onto a wrapper. Advantageously the tracking means is a paper tracking guide and is positioned on a wrapper feed path before the assembly for transferring lengths of web material onto a wrapper.

Preferably the apparatus comprises a drive roller to feed a wrapper along a wrapper feed path. Advantageously the drive roller is adjacent a pressure roller, the position of the pressure roller and the drive roller allowing the wrapper to be fed therebetween.

It is preferred that the apparatus comprises a tensioning means. The tensioning means must be capable of maintaining the tension in the wrapper fed along a wrapper feed path to the assembly for transferring lengths of web material onto a wrapper. Most preferably the tensioning means comprises a roller and a moveable arm, movement of which arm causes the speed of feed of the wrapper to be altered.

Suitably the apparatus comprises a heating means. Preferably the heating means is a heater capable of heating the wrapper having web material thereon and securely bonding the web material to the wrapper and/or removing unbound flavourant from the web material.

In a second aspect of the invention the adhering means comprises pressure exerting means. Preferably the pressure exerting means comprises a means capable of applying pressure to a wrapper, the wrapper having a length of web material thereon. More preferably the pressure exerting means comprises a pinch roller capable of pressing the wrapper to adhere the web material to the wrapper. Advantageously the pinch roller comprises a belt and a guide means, the belt being positioned about the guide means. More advantageously the pinch roller comprises a plurality of guide means, the guide means being guide rollers. Most preferably the pressure exerting means comprises a plurality of pinch rollers.

In order that the subject invention may be easily understood and readily carried into effect, reference will now be made, by way of example, to the accompanying diagrammatic drawings, in which:

Figure 1 shows a cross-section longitudinally through a smoking article according to the invention;

Figure 2 shows a cross-section through the smoking article of Figure 1 along line x-x;

Figure 3 shows a cross-section longitudinally through a smoking article according to a further embodiment of the invention;

Figure 8 shows a cross-section through a part of the apparatus of Figure 7; and

Figure 9 shows an apparatus for applying web material to a wrapper according to a further embodiment of the invention.

Figure 1 shows a smoking article (1) according to the invention in longitudinal cross-section. The smoking article (1) comprises a rod of smokable material (2) circumscribed by a cigarette wrapper (3). A filter (4) is positioned at the mouth end of the smoking article (1). The filter (4) is attached to the rod of smokable material (2) by a tipping paper (5) as is usual in the art. The smoking article (1) has mentholated carbon paper (6) located at an end thereof. The carbon contained in the mentholated carbon paper (6) stabilises and retains the menthol flavourant. The mentholated carbon paper (6) circumscribes the entire circumference of the smoking article (1). The cigarette wrapper (3) surrounds the rod of smokable material (2) and the mentholated carbon paper (6). The end at which the mentholated carbon paper (6) is located corresponds to the mouth end of the smoking article (1).

Upon smoking, the smoking article (1) is lit at one end, such as, for example, an end furthest from the mentholated carbon paper (6) and smoke is drawn along the rod of smokable material (2) to the consumer. Initially, as smoke passes along the smoking article (1) no menthol flavourant is released from the mentholated carbon paper (6) as a result of the smoke temperature being insufficient to cause menthol to be released from the carbon. As the smoking article (1) is further smoked and the burning coal advances along the rod of smokable material (2) towards the mouth end of the smoking article (1) the mentholated carbon paper (6) is contacted by the coal and the temperature is sufficiently high to release the menthol flavourant from the mentholated carbon paper (6). At this point the consumer receives sensorial characteristics including the menthol-flavourant therein.

Figure 2 shows a transverse cross-section through the smoking article (1) of Figure 1 along line x-x showing the wrapper (3) circumscribing the rod of smokable material (2) and the mentholated carbon paper (6) extending around the entire circumference of the rod of smokable material (2) interiorly of the wrapper (3).

Figure 3 shows a smoking article (1) in longitudinal cross-section, in which a rod of smokable material (2) is circumscribed by a wrapper (3). A filter (4) is located at the mouth end of the smoking article (1) and is attached to the rod of smokable material (2) by a tipping paper (5). The smoking article (1) has a patch of mentholated carbon paper (6) located at one end thereof. The end at which the mentholated carbon paper (6) is located corresponds to the mouth end of the smoking article (1). The patch of mentholated carbon paper (6) extends over only part of the circumference of the smoking article (1).

Figure 4 shows a transverse cross-section through the smoking article (1) of Figure 3 along line y-y, showing the wrapper (3) circumscribing the rod of smokable material (2) and the mentholated carbon paper (6) extending only partially around the circumference of the rod of smokable material (2) interiorly of the wrapper (3).

Figure 5 shows a smoking article (1) in cross-section, in which a rod of smokable material (2) is circumscribed by a wrapper (3). A filter (4) is located at the mouth end of the smoking article (1) and is attached to the rod of smokable material (2) by a tipping paper (5). The smoking article (1) has a patch of mentholated carbon paper (6) located towards one end

thereof. The end towards which the mentholated carbon paper (6) is located corresponds to the mouth end of the smoking article (1). The mentholated carbon paper (6) is positioned at a distance from the end of the smoking article (1) corresponding to the mouth end thereof, such that the mentholated carbon paper (6) is near to, but not at, the end of the smoking article (1).

A system for producing flavoured carbon paper is shown in Figure 6. A bobbin of activated carbon paper (1) is held on a mandrel (2). A brake arm (3) is adjacent to the mandrel (2) and allows the mandrel (2) to rotate and feed carbon paper (4) when under tension. When the carbon paper (4) is not under tension the brake arm (3) acts against the drum of the mandrel (2). The mandrel (2) is known as an "unwind" mandrel. The carbon paper (4) is fed around a number of guide rollers (5) to ensure that the carbon paper (4) is directed along the correct path. The brake arm is connected to two of the guide rollers (5a, 5b), which guide rollers remain in a lowered position when the carbon paper (4) is slack and serve to keep the brake arm (3) in contact with the drum of the unwind mandrel. When contacting the drum the brake arm (3) prevents the unwind mandrel rotating and feeding carbon paper (4) therefrom. This action ensures that the carbon paper (4) is maintained in a pre-tensioned state and serves to prevent the inertia of the bobbin over-feeding the carbon paper (4). When the carbon paper (4) is in a pre-tensioned state the two guide rollers (5a, 5b) are raised by the tensioned paper and serve to lift the brake arm (3) in contact therewith, resulting in the brake arm (3) being pivoted away from the drum of the unwind mandrel and allowing the carbon paper (4) to be fed from the mandrel. Two guide rollers (5a, 5b) are utilised in the brake arm assembly to halve the force on the paper at each point, thus reducing the risk of the paper breaking.

An encoder (6) is positioned adjacent to the web material. The encoder (6) is an incremental rotary encoder and contacts the web material such that movement of the carbon paper (4) causes a wheel (not shown) of the encoder (6) to rotate. The number of turns of the wheel of the encoder (6) enables the speed of paper feed from the bobbin to be measured by the encoder (6) and signals to be sent from the encoder (6) to a flavourant applicator apparatus (7). The signals sent from the encoder (6) to the flavourant applicator apparatus (7) cause the flavourant applicator apparatus (7) to adjust the application of flavourant to the carbon paper (4) according to the speed of feed of the carbon paper (4).

The flavourant applicator apparatus (7) comprising a flavourant applicator head (8), a flavourant supply line (9), a flavourant pump (11) and a flavourant source (10) positioned on the transport path of the carbon paper (4). A suitable flavourant applicator apparatus is, for example, the CFA 1000 Cigarette Flavour Application System of C.B.Kaymich & Co. Ltd. The carbon paper (4) passes beneath the flavourant applicator head (8) which is connected by supply line (9) to the flavourant source (10). Flavourant such as, for example, menthol, is pumped by the flavourant pump (11) from the flavourant source (10) in a molten state along heated supply line (9) to the applicator head (8). The applicator head (8) has 8 orifices in the underside thereof through which the flavourant passes onto a surface of the carbon paper (4). The applicator head has an interchangeable plate therein having orifices thereon, it being possible to replace the plate with another plate having a different number/size/pattern of orifices therein. The flavourant is adsorbed into the activated carbon granules of the carbon paper (4). The flavoured carbon paper (12) is fed over a guide roller (5) onto a mandrel (13), which mandrel (13) rotates to wind the flavoured carbon paper (12) around the mandrel (13). The mandrel (13) is known as a "rewind mandrel". The mandrel (13) is driven by a motor (14). The speed of the motor is controlled to maintain a constant web material speed. When all of the carbon paper (4) from bobbin (1) has had flavourant applied thereto and has been fully rewound onto mandrel (13) the flavoured carbon paper is allowed to equilibrate to ensure that the flavourant is evenly distributed in the web material, as far as is possible. This equilibration process is known as "bulking". The paper is then ready to be incorporated into smoking articles according to the present invention.

Figure 7 shows a system for applying patches of carbon paper onto a cigarette wrapper. Flavoured carbon paper (1) is supplied from a bobbin (2) over guide rollers (3). A bobbin brake arm (4) positioned between the bobbin (2) and a guide roller acts to maintain the carbon paper (1) in a pre-tensioned state and serves to prevent the inertia of the rotating bobbin (2) over-feeding the carbon paper (1). The carbon paper (1) is fed along a feed path over a series of rollers, including a metering roller (5) that controls the speed at which the carbon paper (1) is fed. The metering roller (5) is driven by a belt (not shown) and is adjacent a rubbing roller (6) which is biased towards the metering roller (5) so that the rubbing roller (6) effectively pinches

the carbon paper (1) and the metering roller (5) feeds the carbon paper (1). A (paper tracking) guide roller (7) is positioned after the metering roller (5) and serves to ensure that the web material is aligned correctly before reaching an adhesive applicator (8).

The adhesive applicator (8) is a gravure gummer (8) comprising two applicator rollers (8a, 8b). The lower applicator roller (8a) is in contact with a well of adhesive and when rotated is coated in adhesive from the adhesive well. The upper applicator roller (8b) is in contact with the lower applicator roller (8a), and via rotation of the upper and lower applicator rollers adhesive is transferred from the lower applicator roller (8a) to the upper applicator roller (8b). The upper applicator roller (8b) is also in contact with the carbon paper (1) and allows adhesive to be transferred from the surface of the upper applicator roller (8b) to a surface of the carbon paper (1). The speed of rotation of the upper and lower applicator rollers of the gravure gummer (8) are timed, in conjunction with the speed of the carbon paper (1) itself, to ensure that adhesive is accurately applied to the carbon paper (1). The adhesive may be applied intermittently to the carbon paper (1) or may be applied continuously. Varying patterns of adhesive application to the carbon paper (1) are achieved by altering the surface of the lower applicator roller (8a). Adhesive may be applied, for example, across the entire surface of the carbon paper (1) or in two lines each of 2mm width at the edges of the carbon paper (1) or spaced approximately 2mm from the edges of the carbon paper (1).

A second (paper tracking) guide roller (9) is positioned before a rotary knife assembly (10) and ensures that the web material is correctly aligned with the suction stations on the drum assembly (11) prior to being cut into sections.

The rotary knife assembly (10) is located adjacent to a drum assembly (11) comprising a vacuum drum. The vacuum drum is rotatable and has a suction force applied to the interior thereof and has a number of holes in the surface thereof to allow the suction force to be conveyed to objects on the surface of the vacuum drum. The rotary knife assembly (10) comprises two knives that rotate and cut across the width of the carbon paper (1) against the single drum assembly (11). The rotary knife assembly (10) is driven by gears from the drum assembly (11) such that the knives correspond to one of six positions on the drum assembly (11). Each of the six positions on the drum assembly (11) corresponds to a patch station on the

surface of the vacuum drum (see Figure 8). The sections of carbon paper (1) produced by the cuts coincide with the six positions on the drum assembly (11). The surface speed of each knife substantially corresponds to the surface speed of the vacuum drum of the drum assembly (11). The length of the patches of web material is controlled by the speed of the web material and the surface speed of the vacuum drum, together with the pitch of patch stations on the vacuum drum. Figure 8 shows a circumferential pitch (13) of the drum assembly (1) and the direction of travel of the rotary knife assembly (10) having knives (12) thereon and the drum assembly (11). The following formula is used to calculate patch length:

$$\text{Patch length} = P \times V_1/V_2$$

wherein P = pitch of stations on vacuum drum (mm)

V_1 = speed of web material (m/min)

V_2 = surface speed of vacuum drum (m/min)

For example, at a speed of 3,000 cuts per minute, a station pitch of 114mm and for a tobacco rod length of 57mm,

$$V_2 = 3000 \times 57$$

$$= 171 \text{ m/min}$$

$$\text{Therefore, Patch length} = 114 \times 90/171$$

$$= 60\text{mm}$$

After being cut into patches the carbon paper (1) is held on the rotatable vacuum drum of the drum assembly (11). The vacuum drum having the sections of carbon paper (1) held on the outer surface thereof rotates to allow transfer of the carbon paper (1) to a cigarette paper (14). The vacuum drum rotates with a surface speed corresponding to the speed of the cigarette paper (14) to which the lengths of web material are transferred and accelerates the sections of carbon paper thereon so that the sections of carbon paper are transferred to the cigarette paper (14) at the same speed at which the cigarette paper (14) is running.

Cigarette paper (14) is held on a cigarette paper bobbin (15), from which bobbin (15) the cigarette paper (14) is supplied over guide rollers (16). A bobbin brake arm (17) acts to maintain the tension of the cigarette paper (14), in the same manner as previously described for the carbon paper. The cigarette paper (14) is fed along a paper feed path comprising a number

of guide rollers (16) which serve to control the direction of feed of the cigarette paper (14). A paper tracking guide means (18) is located along the paper feed path between guide rollers (16) and allows precise tracking control of the supply of the cigarette paper (14). The paper tracking guide means (18) may be adjusted to change the path of the cigarette paper (14), allowing the cigarette paper (14) to be aligned with the sections of carbon paper transferred from the rotatable drum of the drum assembly (11).

As the cigarette paper (14) passes over the drum assembly (11) sections of carbon paper held on the surface of the rotatable drum are transferred to the surface of the cigarette paper (14) contacting the carbon paper sections. The sections of carbon paper are transferred to and held by the cigarette paper (14) as a result of the adhesive on the surface of the carbon paper sections. The cigarette paper (14) contacts the drum assembly (11) at an angle as shown in Figure 7, whereby the angle denoted by θ in Figure 7 is greater than 180 degrees and is preferably approximately 225 degrees. An increased angle allows the cigarette paper (14) to be in contact with the drum assembly (11) for a longer time. Contact between the cigarette paper (14) and the drum assembly (11) is effected by their respective positions and the tension of the cigarette paper (14) which allows some degree of slippage of the cigarette paper (14) relative to the drum assembly (11). This slippage allows the patch position to be corrected relative to the cut of the smoking article on a cigarette making machine. Subsequent to the transfer of the carbon paper sections to the cigarette paper (14) the cigarette paper (14) passes over two guide rollers (16) before passing between a feed roller (19) and a pinch roller (20). The feed roller (19) feeds the cigarette paper (14) in response to demand from the cigarette making machine. The feed roller (19) is driven independently from the drum assembly and the patch feed system. The pressure exerted on the cigarette paper (14) by the feed roller (19) and the pinch roller (20) aids in the adherence of the patches to the cigarette paper (14). The cigarette paper (14) then passes over a dancing arm arrangement (21), which arrangement serves to control the speed at which the cigarette paper (14) is fed and the tension of the cigarette paper (14) by attempting to maintain a constant arm position.

A sensor (22) is mounted immediately prior to the garniture (23) of the cigarette making machine and serves to detect the position of the patch on the cigarette paper (14) in relation to

the cutting knife of the cigarette making machine. The speed of the drum assembly (11) may be altered relative to the speed of the cigarette paper (14) to ensure that the patch is in the correct position on the cigarette paper (14), in relation to the cigarette making machine and accordingly will be correctly positioned in the finished smoking article. This control system automatically effects small changes in drum assembly speed.

Optionally, a heater (24) is positioned on the feed path of the cigarette paper (14) and heats the cigarette paper (14) particularly but not exclusively in the region of the carbon paper (1) to securely bond the carbon paper to the cigarette paper (14). If heat-activatable adhesive is used the heat from the heater (24) activates the adhesive to ensure an effective bond. The heater (24) also serves to remove unbound menthol from the web material.

The cigarette paper having carbon paper attached thereto proceeds to a conventional rod forming garniture, which rod forming garniture may be, for example, a cigarette making machine.

Figure 9 shows a further system for feeding carbon paper onto a wrapper. Flavoured carbon paper (1) is fed from a bobbin (2) along a feed path. The carbon paper (1) is fed past a metering roller (3) that serves to control the speed of supply of the carbon paper (1) in the same manner as previously described in relation to Figure 7. A rotary knife assembly (4) having a knife thereon cuts the carbon paper (1) into lengths. The lengths of carbon paper are held on the surface of the vacuum drum of a drum assembly (5) by suction forces within the drum. The suction drum rotates to transfer the lengths of carbon paper from the rotary knife assembly (4) to a cigarette paper (6) and deposit the carbon paper lengths onto a surface of the cigarette paper (6).

Cigarette paper or wrapper is held on a bobbin (7) and is supplied therefrom along a paper feed path. The cigarette paper (6) is fed over a number of guide rollers (8) before passing a drag roller (9) that serves to maintain the tension of the cigarette paper (6). The cigarette paper (6) passes the drum assembly (5) and contacts the carbon paper lengths held on the surface thereof. A release of the suction from the vacuum drum causes the leading edge of the length of carbon paper to leave the vacuum drum. The cigarette paper (6) and the leading edge of the length of carbon paper enter between a pair of pinch belts (10, 10), one on each side of

the cigarette paper feed path. The pinch belts (10) squeeze the cigarette paper (6) and carbon paper lengths therebetween and serve to press the lengths of carbon paper onto the cigarette paper (6). As the cigarette paper (6) and the length of carbon paper advance through the pinch belts (10, 10) the trailing edge of the length of carbon paper is released from the suction drum and is also pressed onto the cigarette paper (6). Each pinch belt (10) comprises a belt running around two guide rollers, each located at an opposite end of the pinch belt (10). Further rollers operate to drive the pinch belts (10) and to maintain tension therein.

The cigarette paper having carbon paper thereon is then fed to a rod forming garniture (11). The rod forming garniture (11) is, for example, a cigarette making machine.
